Lead Evaluation

A lead evaluation was performed as part of the Naval Station Guantanamo Bay (NSGB) Human Health Risk Assessment (HHRA). Though lead is a naturally occurring compound in nature, industrial activity and human-made products can increase the amount of lead people are exposed to in the workplace and at home – potentially causing harmful health effects. Lead exposure is of particular concern to children and pregnant adult females, as an elevated blood lead level (BLL) can result in health complications in a child or fetus. A BLL of 10 micrograms per deciliter (10 µg/dL) has been the United States Environmental Protection Agency (USEPA) threshold level of concern, requiring intervention if a child’s BLL reached or exceeded this concentration (USEPA 2016). The USEPA set a post-remediation goal that the likelihood of a child having an elevated BLL (10 µg/dL or greater) should be no more than five percent (USEPA 2016). More recently, researchers have found that harmful health effects can occur at lower BLLs, leading the Center for Disease Control (CDC) and other organizations to recommend five micrograms per deciliter (5 µg/dL) as the new BLL of concern in adults and children (Agency for Toxic Substances and Disease Registry [ATSDR] 2016).

Based on soil samples collected at NSGB in October of 2015, lead background (pre-existing) levels in soil at NSGB ranged from 5.6 micrograms of lead per gram of soil (5.6 µg Pb/g) to 42 µg Pb/g. It is assumed that soil lead concentrations greater than 42 µg Pb/g can most likely be attributed to human activity at NSGB over time.

To assess whether or not lead levels at NSGB pose a risk to human health, a lead evaluation was performed using two USEPA lead models: the Integrated Exposure Uptake Biokinetic (IEUBK) model and the Adult Lead Methodology (ALM) model. The IEUBK model was used to evaluate lead risk in children (USEPA 2010). The ALM model was used to evaluate lead risk in adult workers and estimate the probability of a pregnant worker’s fetus having a BLL above a specified target value (USEPA 1996). The modeling results are shown below. The complete model of inputs and outputs included as Attachment 1.

Lead Exposure Evaluation for Children Outside of Camp Justice

The IEUBK analysis was performed with the assumption that children at NSGB would spend the majority of time in residential areas. For site-specific inputs, the highest residential values available for air lead concentration and soil lead concentration were used. No sampled or modeled drinking water data were available for residential areas, so the maximum lead concentration in tap water from Camp Justice was used in the model. The results from the IEUBK Model for the BLL for a child is presented in the table below. Based on the worst-case scenario (highest) lead values, all projected BLLs are below the 10 µg/dL level of concern, as well as being below the more sensitive 5 µg/dL lead concentration.

Site-Specific Inputs for IEUBK Model

Parameter	Value	Units
Outdoor Air Lead Concentration	3.7E-04	µg Pb / m ³
Drinking Water Lead Concentration	11	µg Pb / L
Soil Lead Concentration	3.2E-06	µg Pb / g

Note: Model inputs that were not site-specific were USEPA default values.

Blood Lead Level for Child (Results from IEUBK Model)

Age of Child (Year)	BLL (µg/dL)	BLL Exceeds 10 µg/dL? (Yes/No)	BLL Exceeds 5 µg/dL? (Yes/No)
0.5-1	1.2	No	No
1-2	1.5	No	No
2-3	1.4	No	No
3-4	1.4	No	No
4-5	1.3	No	No
5-6	1.3	No	No
6-7	1.2	No	No

Note: Full model outputs can be found below in Attachment 1.

Lead Exposure Evaluation for Adults Working Inside and Outside of Camp Justice

The ALM analysis was performed to evaluate the worst-case lead exposure risks for an NSGB worker (and a pregnant worker’s fetus); both inside and outside of Camp Justice work environments were considered. Model inputs included the highest lead values available for inside and outside Camp Justice (from measured and modeled NSGB data), along with the maximum days per year a worker inside and outside of Camp Justice would be at an occupational site. Based on the results of the ALM model, adult workers in both scenarios would have a BLL less than the 10 µg/dL level of concern, and less than the more sensitive 5 µg/dL blood lead concentration. In both scenarios, the probability that a fetal blood concentration would exceed 10 µg/dL was extremely low (0.3%) or zero. With the worst-case lead exposure for an inside of Camp Justice worker, the highest probability that a fetal blood concentration would exceed 5 µg/dL was 5.7%.

Site-Specific Inputs for ALM Model

Scenario	Soil Lead Concentration (µg/g)	Soil Ingestion Rate (g/day)	Exposure Frequency (days/year)
Camp Justice Worker	260	0.100	350
Outside Camp Justice Worker	5.1E-06	0.100	250

Note: All other model inputs were USEPA default values.

Blood Lead Level for Adult Worker and Probability of Fetal Blood Lead Level Exceeding Level of Concern (Results from ALM Model)

Scenario	BLL of Adult Worker, Geometric Mean (µg/dL)	Probability that Fetal BLL Exceeds 10 µg/dL	Probability that Fetal BLL Exceeds 5 µg/dL
Camp Justice Worker	2.2	0.3%	5.7%
Outside Camp Justice Worker	1.0	0.0%	0.2%

Note: Full model outputs can be found below in Attachment 1.

Lead Exposure Conclusion

Based on available data and results from the USEPA IEUBK and ALM models, the lead risks to children and adult workers at NSGB are below levels of concern.

Appendix J

ATSDR ToxFAQs™ for Select COPCs

NAVY AND MARINE CORPS PUBLIC HEALTH CENTER

PREVENTION AND PROTECTION START HERE

This page has been left blank to allow for double-sided printing

This fact sheet answers the most frequently asked health questions (FAQs) about arsenic. For more information, call the CDC Information Center at 1-800-232-4636. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to higher than average levels of arsenic occur mostly in the workplace, near hazardous waste sites, or in areas with high natural levels. At high levels, inorganic arsenic can cause death. Exposure to lower levels for a long time can cause a discoloration of the skin and the appearance of small corns or warts. Arsenic has been found in at least 1,149 of the 1,684 National Priority List (NPL) sites identified by the Environmental Protection Agency (EPA).

What is arsenic?

Arsenic is a naturally occurring element widely distributed in the earth's crust. In the environment, arsenic is combined with oxygen, chlorine, and sulfur to form inorganic arsenic compounds. Arsenic in animals and plants combines with carbon and hydrogen to form organic arsenic compounds.

Inorganic arsenic compounds are mainly used to preserve wood. Copper chromated arsenate (CCA) is used to make "pressure-treated" lumber. CCA is no longer used in the U.S. for residential uses; it is still used in industrial applications. Organic arsenic compounds are used as pesticides, primarily on cotton fields and orchards.

What happens to arsenic when it enters the environment?

- Arsenic occurs naturally in soil and minerals and may enter the air, water, and land from wind-blown dust and may get into water from runoff and leaching.
- Arsenic cannot be destroyed in the environment. It can only change its form.
- Rain and snow remove arsenic dust particles from the air.
- Many common arsenic compounds can dissolve in water. Most of the arsenic in water will ultimately end up in soil or sediment.
- Fish and shellfish can accumulate arsenic; most of this arsenic is in an organic form called arsenobetaine that is much less harmful.

How might I be exposed to arsenic?

- Ingesting small amounts present in your food and water or breathing air containing arsenic.
- Breathing sawdust or burning smoke from wood treated with arsenic.
- Living in areas with unusually high natural levels of arsenic in rock.
- Working in a job that involves arsenic production or use, such as copper or lead smelting, wood treating, or pesticide application.

How can arsenic affect my health?

Breathing high levels of inorganic arsenic can give you a sore throat or irritated lungs.

Ingesting very high levels of arsenic can result in death. Exposure to lower levels can cause nausea and vomiting, decreased production of red and white blood cells, abnormal heart rhythm, damage to blood vessels, and a sensation of "pins and needles" in hands and feet.

Ingesting or breathing low levels of inorganic arsenic for a long time can cause a darkening of the skin and the appearance of small "corns" or "warts" on the palms, soles, and torso.

Skin contact with inorganic arsenic may cause redness and swelling.

Almost nothing is known regarding health effects of organic arsenic compounds in humans. Studies in animals show that some simple organic arsenic

Arsenic

CAS # 7440-38-2

compounds are less toxic than inorganic forms. Ingestion of methyl and dimethyl compounds can cause diarrhea and damage to the kidneys.

How likely is arsenic to cause cancer?

Several studies have shown that ingestion of inorganic arsenic can increase the risk of skin cancer and cancer in the liver, bladder, and lungs. Inhalation of inorganic arsenic can cause increased risk of lung cancer. The Department of Health and Human Services (DHHS) and the EPA have determined that inorganic arsenic is a known human carcinogen. The International Agency for Research on Cancer (IARC) has determined that inorganic arsenic is carcinogenic to humans.

How can arsenic affect children?

There is some evidence that long-term exposure to arsenic in children may result in lower IQ scores. There is also some evidence that exposure to arsenic in the womb and early childhood may increase mortality in young adults.

There is some evidence that inhaled or ingested arsenic can injure pregnant women or their unborn babies, although the studies are not definitive. Studies in animals show that large doses of arsenic that cause illness in pregnant females, can also cause low birth weight, fetal malformations, and even fetal death. Arsenic can cross the placenta and has been found in fetal tissues. Arsenic is found at low levels in breast milk.

How can families reduce the risks of exposure to arsenic?

- If you use arsenic-treated wood in home projects, you should wear dust masks, gloves, and protective clothing to decrease exposure to sawdust.
- If you live in an area with high levels of arsenic in water or soil, you should use cleaner sources of water and limit contact with soil.

- If you work in a job that may expose you to arsenic, be aware that you may carry arsenic home on your clothing, skin, hair, or tools. Be sure to shower and change clothes before going home.

Is there a medical test to determine whether I've been exposed to arsenic?

There are tests available to measure arsenic in your blood, urine, hair, and fingernails. The urine test is the most reliable test for arsenic exposure within the last few days. Tests on hair and fingernails can measure exposure to high levels of arsenic over the past 6-12 months. These tests can determine if you have been exposed to above-average levels of arsenic. They cannot predict whether the arsenic levels in your body will affect your health.

Has the federal government made recommendations to protect human health?

The EPA has set limits on the amount of arsenic that industrial sources can release to the environment and has restricted or cancelled many of the uses of arsenic in pesticides. EPA has set a limit of 0.01 parts per million (ppm) for arsenic in drinking water.

The Occupational Safety and Health Administration (OSHA) has set a permissible exposure limit (PEL) of 10 micrograms of arsenic per cubic meter of workplace air ($10 \mu\text{g}/\text{m}^3$) for 8 hour shifts and 40 hour work weeks.

ToxFAQs™ Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaqs/index.asp>.

ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about formaldehyde. For more information, call the CDC Information Center at 1-800-232-4636. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important that you understand this information because this substance may cause harm to you if you are exposed to it. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Everyone is exposed to small amounts of formaldehyde in air and some foods and products. Formaldehyde can cause irritation of the eyes, nose, and throat and neurological effects. Formaldehyde has been found in at least 29 of the 1,669 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is formaldehyde?

At room temperature, formaldehyde is a colorless, flammable gas that has a distinct, pungent smell. Small amounts of formaldehyde are naturally produced by plants, animals, and humans.

It is used in the production of fertilizer, paper, plywood, and urea-formaldehyde resins. It is also used as a preservative in some foods and in many house-hold products, such as antiseptics, medicines, and cosmetics.

What happens to formaldehyde when it enters the environment?

- Once formaldehyde is in the air, it is quickly broken down, usually within hours.
- Formaldehyde dissolves easily but does not last a long time in water.
- Formaldehyde evaporates from shallow soils.
- Formaldehyde does not build up in plants and animals.

How might I be exposed to formaldehyde?

- The primary way you can be exposed to formaldehyde is by breathing air containing it.
- Releases of formaldehyde into the air occur from industries using or manufacturing formaldehyde, wood products (such as particle-board, plywood, and furniture), automobile exhaust, cigarette smoke, paints and varnishes, and carpets and permanent press fabrics.
- Indoor air contains higher levels of formaldehyde than outdoor air. Levels of formaldehyde measured

in indoor air range from 0.02–4 parts per million (ppm). Formaldehyde levels in outdoor air range from 0.0002 to 0.006 ppm in rural and suburban areas and 0.001 to 0.02 ppm in urban areas.

- Breathing contaminated workplace air. The highest potential exposure occurs in the formaldehyde-based resins industry.

How can formaldehyde affect my health?

Nasal and eye irritation, neurological effects, and increased risk of asthma and/or allergy have been observed in humans breathing 0.1 to 0.5 ppm. Eczema and changes in lung function have been observed at 0.6 to 1.9 ppm.

Decreased body weight, gastrointestinal ulcers, liver and kidney damage were observed in animals orally exposed to 50–100 milligrams/kilogram/day (mg/kg/day) formaldehyde.

How likely is formaldehyde to cause cancer?

The Department of Health and Human Services (HHS) determined in 2011 that formaldehyde is a known human carcinogen based on sufficient human and animal inhalation studies.

How can formaldehyde affect children?

A small number of studies have looked at the health effects of formaldehyde in children. It is very likely that breathing formaldehyde will result in nose and eye irritation. We do not know if the irritation would occur at lower concentrations in children than in adults.

Formaldehyde

CAS # 50-00-0

There is some evidence of asthma or asthma-like symptoms for children exposed to formaldehyde in homes.

Animal studies have suggested that formaldehyde will not cause birth defects in humans.

How can families reduce the risk of exposure to formaldehyde?

- Formaldehyde is usually found in the air, and levels are usually higher indoors than outdoors. Opening windows and using fans to bring fresh air indoors are the easiest ways to lower levels in the house. Not smoking and not using unvented heaters indoors can lower the formaldehyde levels.
- Formaldehyde is given off from a number of products used in the home. Removing formaldehyde sources in the home can reduce exposure. Providing fresh air, sealing unfinished manufactured wood surfaces, and washing new permanent press clothing before wearing can help lower exposure.

Is there a medical test to show whether I've been exposed to formaldehyde?

Formaldehyde cannot be reliably measured in blood, urine, or body tissues following exposure. Formaldehyde is produced in the body and would be present as a normal constituent in body tissues and fluids.

Has the federal government made recommendations to protect human health?

The US EPA has determined that exposure to formaldehyde in drinking water at concentrations of 10 milligrams/liter (mg/L) for 1 day or 5 mg/L for 10 days is not expected to cause any adverse effects in children.

The US EPA has also determined that a lifetime exposure to 1 mg/L of formaldehyde in drinking water is not expected to cause any adverse health effects.

The Occupational Health and Safety Administration (OSHA) has limited workers' exposure to an average of 0.75 ppm for an 8-hour workday, 40-hour workweek.

The U.S. Department of Housing and Urban Development (HUD) has set standards for formaldehyde emissions in manufactured housing of less than 0.2 ppm for plywood and 0.3 ppm for particle board. The HUD standards are designed to provide an ambient air level of 0.4 ppm or less in manufactured housing.

Polycyclic Aromatic Hydrocarbons (PAHs) - ToxFAQs™

This fact sheet answers the most frequently asked health questions (FAQs) about polycyclic aromatic hydrocarbons (PAHs). For more information, call the CDC Information Center at 1-800-232-4636. This fact sheet is one in a series of summaries about hazardous substances and their health effects. This information is important because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to polycyclic aromatic hydrocarbons usually occurs by breathing air contaminated by wild fires or coal tar, or by eating foods that have been grilled. PAHs have been found in at least 600 of the 1,430 National Priorities List (NPL) sites identified by the Environmental Protection Agency (EPA).

What are polycyclic aromatic hydrocarbons?

(Pronounced pŏl'ī-sī'klīk ār'ə-măt'īk hī'drə-kar'bənz)

Polycyclic aromatic hydrocarbons (PAHs) are a group of over 100 different chemicals that are formed during the incomplete burning of coal, oil and gas, garbage, or other organic substances like tobacco or charbroiled meat. PAHs are usually found as a mixture containing two or more of these compounds, such as soot.

Some PAHs are manufactured. These pure PAHs usually exist as colorless, white, or pale yellow-green solids. PAHs are found in coal tar, crude oil, creosote, and roofing tar, but a few are used in medicines or to make dyes, plastics, and pesticides.

What happens to PAHs when they enter the environment?

- PAHs enter the air mostly as releases from volcanoes, forest fires, burning coal, and automobile exhaust.
- PAHs can occur in air attached to dust particles.
- Some PAH particles can readily evaporate into the air from soil or surface waters.
- PAHs can break down by reacting with sunlight and other chemicals in the air, over a period of days to weeks.
- PAHs enter water through discharges from industrial and wastewater treatment plants.

- Most PAHs do not dissolve easily in water. They stick to solid particles and settle to the bottoms of lakes or rivers.
- Microorganisms can break down PAHs in soil or water after a period of weeks to months.
- In soils, PAHs are most likely to stick tightly to particles; certain PAHs move through soil to contaminate underground water.
- PAH contents of plants and animals may be much higher than PAH contents of soil or water in which they live.

How might I be exposed to PAHs?

- Breathing air containing PAHs in the workplace of coking, coal-tar, and asphalt production plants; smokehouses; and municipal trash incineration facilities.
- Breathing air containing PAHs from cigarette smoke, wood smoke, vehicle exhausts, asphalt roads, or agricultural burn smoke.
- Coming in contact with air, water, or soil near hazardous waste sites.
- Eating grilled or charred meats; contaminated cereals, flour, bread, vegetables, fruits, meats; and processed or pickled foods.
- Drinking contaminated water or cow's milk.
- Nursing infants of mothers living near hazardous waste sites may be exposed to PAHs through their mother's milk.

Polycyclic Aromatic Hydrocarbons

How can PAHs affect my health?

Mice that were fed high levels of one PAH during pregnancy had difficulty reproducing and so did their offspring. These offspring also had higher rates of birth defects and lower body weights. It is not known whether these effects occur in people.

Animal studies have also shown that PAHs can cause harmful effects on the skin, body fluids, and ability to fight disease after both short- and long-term exposure. But these effects have not been seen in people.

How likely are PAHs to cause cancer?

The Department of Health and Human Services (DHHS) has determined that some PAHs may reasonably be expected to be carcinogens.

Some people who have breathed or touched mixtures of PAHs and other chemicals for long periods of time have developed cancer. Some PAHs have caused cancer in laboratory animals when they breathed air containing them (lung cancer), ingested them in food (stomach cancer), or had them applied to their skin (skin cancer).

Is there a medical test to show whether I've been exposed to PAHs?

In the body, PAHs are changed into chemicals that can attach to substances within the body. There are special tests that can detect PAHs attached to these substances in body tissues or blood. However, these tests cannot tell whether any health effects will occur or find out the extent or source of your exposure to the PAHs. The tests aren't usually available in your doctor's office because special equipment is needed to conduct them.

Where can I get more information?

For more information, contact the Agency for Toxic Substances and Disease Registry, Division of Toxicology and Human Health Sciences, 1600 Clifton Road NE, Mailstop F-57, Atlanta, GA 30329-4027.

Phone: 1-800-232-4636.

ToxFAQs™ Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaqs/index.asp>.

ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

Has the federal government made recommendations to protect human health?

The Occupational Safety and Health Administration (OSHA) has set a limit of 0.2 milligrams of PAHs per cubic meter of air (0.2 mg/m³). The OSHA Permissible Exposure Limit (PEL) for mineral oil mist that contains PAHs is 5 mg/m³ averaged over an 8-hour exposure period.

The National Institute for Occupational Safety and Health (NIOSH) recommends that the average workplace air levels for coal tar products not exceed 0.1 mg/m³ for a 10-hour workday, within a 40-hour workweek. There are other limits for workplace exposure for things that contain PAHs, such as coal, coal tar, and mineral oil.

Glossary

Carcinogen: A substance that can cause cancer.

Ingest: Take food or drink into your body.

Appendix K

Cancer Risk and Hazard Index Risk Drivers by Exposure Pathway and Chemical

This page has been left blank to allow for double-sided printing.

Introduction

The tables presented in this appendix summarize the cancer risks and noncancer hazard indices presented in Appendix H by the exposure pathways and chemicals responsible for the majority of the risk. These tables are presented in the same order as the tables presented in Appendix H to facilitate comparison of the results between the two appendices. For example, Table K-1 corresponds to Table H-385, Table K-2 corresponds to Table H-386, and Table K-3 corresponds to Table H-387.

This page has been left blank to allow for double-sided printing.

Table K-1 (Percentage of Risk Contributed by Exposure Pathways and Chemicals)

ACI Lifetime (yrs)	16
Exposure Duration (yrs)	9 Months

This page has been left blank to allow for double-sided printing.

Evaluation of Infant Exposures to Dioxins/Furans (as 2,3,7,8-TCDD Toxic Equivalent) at Naval Station Guantanamo Bay via Breast Milk

As recommended in the United States Environmental Agency (USEPA) Combustor Protocol, the potential risk to an infant via ingestion of dioxin/furans¹ (dioxins) in breast milk was evaluated by comparing the estimated average daily dose (ADD) of dioxins for a nursing infant to the United States (US) national average background² exposure level of 93 picograms per kilogram body weight per day (pg/kg-day) (USEPA 2005). This target ADD is recommended by the USEPA, and is based on a measured background level of dioxins in breast milk of 25 ppt (USEPA 2005). If exposures due to the Air Curtain Incinerator (ACI) emissions during the exposure duration of concern are low compared to background exposures, then the emissions are not expected to cause an increase in noncancer effects.

Note: The USEPA typically evaluates noncancer effects of chemicals by comparing exposure levels to health-based reference doses or concentrations. However, the USEPA has not developed noncancer benchmarks for dioxins. Therefore, this alternative USEPA-recommended approach was used to evaluate dioxins.

Concentrations of dioxins in breast milk fat were estimated from the total maternal ADD. The maternal ADD of dioxins was calculated based on total intake from direct contact exposures (ingestion of fish, dermal contact with soil, and incidental soil ingestion) and inhalation (see Tables L-1 and L-2). Maternal exposures were based on the Maximum Point of Impingement (MPOI)³ (i.e., the worst case residential location) located Outside Camp Justice. A 25-year residential scenario was assumed based on a 30-year ACI operational time frame (again worst case assumptions for this human health risk assessment).

The ADD, as 2,3,7,8-TCDD toxic equivalent (TEQ), was calculated as 0.1 in pg/kg-day. The dose is several orders of magnitude lower than the US background level of 93 pg/kg-day. Since the calculated daily dose is for a maximum exposure scenario, daily doses for other exposure scenarios would be lower. It was therefore concluded that incinerator-related exposure of infants to dioxins was below background level exposures.

Reference:

USEPA 2005. Human Health Risk Assessment Protocol for Hazardous Waste Combustion Facilities.
USEPA Office of Solid Waste. September.

¹ Calculated as 2,3,7,8-TCDD TEQ. Also includes dioxin-like polychlorinated biphenyls (PCBs): PCB-77, PCB-81, PCB-105, PCB-114, PCB-118, PCB-123, PCB-126, PCB-156, PCB-157, PCB-167, PCB-169, and PCB-189.

² The 25-ppt 2,3,7,8-TCDD TEQ is the sum of the average breast milk concentration of 18-ppt TEQ from PCDD/PCDFs and 7-ppt TEQ from co-planar, dioxin-like PCBs. After normalization for infant body weight, this breast milk concentration of 25 ppt TEQ results in an average, background intake for the infant of 93 (pg/kg-day) of 2,3,7,8-TCDD TEQ (USEPA 2005).

³ The MPOI represents the location on the receptor grid (with the exception of the Air Curtain Incinerator area, Guantanamo Bay, or Caribbean Sea) where the highest concentration/deposition is predicted to occur. See Section 2 of the NSGB HHRA for more information.
